Motivation (Parallel and Multiprocessor Jobs)

- ▶ Parallel jobs require more than one processor at the same time.
- ▶ Some jobs can not be performed asynchronously on modern computers. Such situation takes place in multiprocessor graphics cards, where the memory capacity of one processor is not sufficient.
- ▶ Many computer systems offer some kinds of parallelism. The energy efficient scheduling of parallel jobs arises in testing and reliable computing, parallel applications on graphics cards, computer control systems and others.

Speed Scaling Scheduling

Processors and Jobs

$m = 2$ speed-scalable processors

$\mathcal{J} = \{1, \dots, n\}$ is the set of jobs:

V_j is the processing volume (work) of job j

$size_j$ is the number of processors required by job j

$W_j := \frac{V_j}{size_j}$ is the work on one processor

Parameters

Preemption and migration are characterized for the systems with single image of the memory.

Non-preemptive instances arise in systems with distributed memory.

Homogeneous Model in Speed-scaling

If a processor runs at speed s then the energy consumption is s^α units of energy per time unit, where $\alpha > 1$ is a constant (practical studies show that $\alpha \leq 3$).

It is supposed that a continuous spectrum of processor speeds is available.

E is the energy budget.

The aim is to find a feasible schedule with the minimum total completion time so that the energy consumption is not greater than a given energy budget.

Convex Program (KKT-conditions)

Two-processor Jobs

$$\frac{1}{2} \sum_{i=1}^n (n - i + 1) p_{\pi_i} \rightarrow \min,$$
$$\sum_{i=1}^n (V_{\pi_i})^\alpha p_{\pi_i}^{1-\alpha} = E.$$

Single-processor Jobs

$$\sum_{j \in \mathcal{J}} C_j(\pi) = \sum_{j=1}^{\frac{n}{2}} \left(\frac{n}{2} - j + 1 \right) (p_{\pi_{2j-1}} + p_{\pi_{2j}}) \rightarrow \min,$$
$$\sum_{j \in \mathcal{J}} p_j^{1-\alpha} (V_j)^\alpha = E.$$

NP-hardness

Even-Odd Partition Problem

$A = \{a_1, a_2, \dots, a_{2n_0}\}$ is the ordered set such that

$$\sum_{a_i \in A} a_i = 2C, \quad a_i < a_{i+1}, \quad i = 1, \dots, 2n_0 - 1$$

$$a_{2i+1} > 3a_{2i} \quad \text{for } i = 1, \dots, n_0 - 1.$$

Question: whether A can be partitioned into two subsets A_1 and A_2

$$\sum_{a_i \in A_1} a_i = \sum_{a_i \in A_2} a_i = C, \quad |A_1| = |A_2| = n_0,$$

A_1 contains only one element from each pair a_{2i-1}, a_{2i} , $i = 1, \dots, n_0$.

Theorem

Problem $P2|size_j, energy| \sum C_j$ is NP-hard.

Algorithm 1

Scheme

Step 1: Given an instance I of $P2|size_j, energy| \sum C_j$, we generate the instance I' with fully-parallelizable jobs, construct optimal schedule S' for jobs, corresponding to non-decreasing order of volumes V_j , and find optimal durations p_j .

Step 2: Calculate processing times of jobs for instance I :

$\frac{2p_j}{size_j}$, $j = 1, \dots, n$. Assign job j to the first available processor if j requires one processor or to the two processors when both of them are available if j is a two-processor job while keeping the order of jobs in non-decreasing of volumes V_j .

Lemma

$$\sum C_j(S') \leq \sum C_j^*.$$

Theorem

A 2-approximate schedule can be found by Algorithm 1 in $O(n \log n)$ time for scheduling problem $P2|size_j, energy| \sum C_j$.

Local improvements

1. Find blocks

2. If a block consists of an odd number of single-processor jobs, move the last job to the next block if possible

Local improvements

1. Find blocks

2. If a block consists of an odd number of single-processor jobs, move the last job to the next block if possible

Local improvements inside blocks

Algorithm 1 with Local Improvements (Algorithm 2)

Step 1. Construct a schedule by Algorithm 1 and find blocks in the solution.

Step 2. Consequently apply the local improvements between blocks.

Step 3. Apply local improvements inside blocks to the given solution.

Step 4. Return the found solution.

Genetic Algorithm

- 1: Construct the initial population of k permutations.
- 2: Until termination condition is met, perform
for $i \leftarrow 1$ to αk
 - 2.1 Select two parent permutations π^1 and π^2 .
 - 2.2 Construct $(\pi^{1'}, \pi^{2'}) = Cross(\pi^1, \pi^2)$.
 - 2.3 Apply insert mutation to permutations $\pi^{1'}$ and $\pi^{2'}$.
 - 2.4 Compute the objective value of the offspring.
- 3: Return the best found solution.

Details

Initial population: problem specific constructive heuristic.

Selection: ranking.

Crossover: OPX.

Stopping criteria: quantity of fitness calculations.

We use the classic restarting rule.

$$\begin{array}{c} 2 \quad 1 \quad | \quad 3 \quad 4 \quad 5 \quad 6 \quad 7 \\ 4 \quad 3 \quad | \quad 6 \quad 2 \quad 7 \quad 1 \quad 5 \\ \chi \quad | \end{array} \quad \longrightarrow \quad \begin{array}{c} 2 \quad 1 \quad | \quad 4 \quad 3 \quad 6 \quad 7 \quad 5 \\ 4 \quad 3 \quad | \quad 2 \quad 1 \quad 5 \quad 6 \quad 7 \\ \chi \quad | \end{array}$$
