# Speed Scaling Scheduling

## Processors and Jobs

2 speed-scalable processors

 $\mathcal{J} = \{1, \ldots, n\}$  is the set of jobs:  $V_i$  is the processing volume (work) of job j  $size<sub>i</sub>$  is the number of processors required by job j  $W_j := \frac{V_j}{size}$  $\frac{v_j}{size_j}$  is the work on one processor  $E$  is the energy budget

#### Parameters

Preemption and migration are characterized for the systems with single image of the memory.

Non-preemptive instances arise in systems with distributed memory.

## Homogeneous Model in Speed-scaling

If a processor runs at speed s then the energy consumption is  $s^{\alpha}$  units of energy per time unit, where  $\alpha > 1$  is a constant (practical studies show that  $\alpha \leq 3$ ).

It is supposed that a continuous spectrum of processor speeds is available.

<span id="page-3-0"></span>The aim is to find a feasible schedule with the minimum total completion time so that the energy consumption is not greater than a given energy budget.

#### Solution

#### Lower Bound

## <span id="page-5-0"></span>Genetic Algorithm (GA) with Generational Scheme

- 1: Construct the initial population  $P^0 = {\pi_j^0}$  of k permutations. Save  $n_e$  individuals with the best objective values as elites of  $P^0$ . Put  $t=0.$
- 2: Until termination condition is met, perform 2.1 for  $i \leftarrow 1$  to  $(k - n_e)/2$ 
	- 2.1.1 Select two parent permutations  $\pi^1$  and  $\pi^2$  using operator  $Sel(P^t)$ .
	- 2.1.2 Construct  $(\pi^{1'} , \pi^{2'}) = Cross(\pi^1, \pi^2)$ .
	- 2.1.3 Apply the mutation operator to constructed permutations:  $Mut(\pi^{1})$ and  $Mut(\pi^{2})$  and save the result as individuals  $\pi^{t+1}_{2i-1}, \pi^{t+1}_{2i}$  for population  $P^{t+1}$ .

- 2.2 Copy elites of  $P^t$  to  $P^{t+1}$  and identify elites of  $P^{t+1}$ . 2.3 Put  $t = t + 1$ .
- 3: Return the best found individual.

## Solution encoding

#### The solutions are encoded by permutations of jobs.

4, 1, 3, 7, 5, 2, 6

## Crossover Operators

## <span id="page-9-0"></span>Mutation Operators

#### Exchange (swap) mutation

Shift (insert) mutation

#### Scramble Mutation Scheme<sup>1</sup>

- 1. Randomly choose  $n_p$  from Poisson distribution with  $\lambda_p$ .
- 2. Apply operator *Mut* for the given genotype  $n_p$  times.

<sup>&</sup>lt;sup>1</sup>Doerr & Ghannane, & Ibn Brahim: Runtime Analysis for Permutation-based Evolutionary Algorithms (2024)-<br>◆ ロ ▶ → 레 ▶ → 草 ▶ → 草 ▶ │ 草 │ ◆) ۹ (^

## Adaptive Technique<sup>2</sup>

- 1: Choose a crossover. The probability of choosing each operator is proportional to its weight.
- 2: Apply chosen crossover to the parent genotypes.
- 3: Update the weight of the chosen crossover:

 $\phi_a =$  $\sqrt{ }$  $\int$  $\mathcal{L}$  $w_1$ , if the new solution is a new global best,  $w_2$ , if the new solution is better than the current one,  $w_3$ , if the new solution is better than one of the parents or both.

$$
\rho_a = \lambda \rho_a + (1 - \lambda) \phi_a.
$$

## Conclusions and Further Research

## Recommendations

- ▶ Apply auto-tuning for parameters of algorithm.
- ▶ Apply adaptive technique to identify the leading crossover operator.
- ▶ Implement optimized version of the leading crossover operator and try to apply scramble mutation.

### Further Plans

- ▶ Generalize the algorithm on permutation problems.
- ▶ Compare with other known algorithms (P.A. Borisovsky, "A parallel "Go with the winners" algorithm for some scheduling problems", 2023; P. Borisovsky, Y. Kovalenko, "A Memetic Algorithm with Parallel Local Search for Flowshop Scheduling Problems", 2020).
